What this means

Each subject seems to decrease airflow under label 4 of pressure, but at label 6 they pick up the volume being inhaled. 1 & 2 reached this in the same way, while 3 instead decreased response time while lowering airflow (i.e. hyperventilating), which I believe indicates there is something under the pressure telling the body to inhale more. While this did not happen under label 4, there must be some level of pressure that elicits this response, which requires more study.

When looking at this data, we can see that as pressure increases from label 2 to 4, the mean air flow tends to increase, but then decrease from 4 to 6. The exception to this is subject three, whose airflow decreased in every level of pressure. For response time, the response time increased for each level of pressure for subjects 1 & 2, but fluctuate like airflow for subject 3. Finally all mean volumes for subjects decreased from 2 to 4, but increased from subjects 4 to 6.
